INTRODUCTION

This service manual was prepared for use by Authorized Warranty Stations and contains service information for Marantz Model 4300 Stereo 2+Quadradial 4 Receiver.

Servicing information and voltage data included in this manual are intended for use by the knowledgeable and experienced technician only. All instruction should be read carefully. No attempt should be made to proceed without a good understanding of the operation in the receiver.

The parts list furnish information by which replacement part may be ordered from the Marantz Company. A simple description is included for parts which can be usually be obtained through local suppliers.

1. SERVICE NOTES

As can be seen from the circuit diagram, the chassis of Model 4300 consists of following units. Each unit mounted on a printed circuit board is described within the square enclosed by a bold dotted line on the circuit diagram.

- | | |
|---|-----------------------------|
| 1. FM Front End | mounted on P.W. Board, P100 |
| 2. AM Tuner | mounted on P.W. Board, P150 |
| 3. FM IF Amplifier | mounted on P.W. Board, P200 |
| 4. MPX Stereo Decoder, Noise and DC Amplifier | mounted on P.W. Board, P300 |
| 5. Phono Amplifier | mounted on P.W. Board, P400 |
| 6. Vari-Matrix | mounted on P.W. Board, P500 |
| 7. Dolby Unit | mounted on P.W. Board, P600 |
| 8. Power Amplifier | mounted on P.W. Board, P700 |
| 9. Power Supply | mounted on P.W. Board, P800 |
| 10. FM CAL. | mounted on P.W. Board, PC01 |
| 11. Tone Amplifier | mounted on P.W. Board, PD01 |
| 12. Buffer and Pre-Amplifier | mounted on P.W. Board, PE01 |
| 13. Tone Control Unit | mounted on P.W. Board, PF01 |
| 14. Balance Control Unit | mounted on P.W. Board, PG01 |
| 15. 400Hz Oscillator and Meter Driver | mounted on P.W. Board, PL01 |
| 16. Phase Convertor | mounted on P.W. Board, PM01 |
| 17. Speaker Protector | mounted on P.W. Board, PN01 |
| 18. Switch Unit | mounted on P.W. Board, PS01 |
| 19. FM De-emphasis | mounted on P.W. Board, PU01 |
| 20. Dolby Terminal | mounted on P.W. Board, PV01 |
| 21. Head Phones | mounted on P.W. Board, PW01 |
| 22. Selector Lamps | mounted on P.W. Board, PY01 |
| 23. Dial Lamps | mounted on P.W. Board, PZ01 |

2. AM TUNER

The AM TUNER portion of the 4300 is composed of one IC circuit (including RF amplifier, local oscillator, mixer, IF amplifier, detector, and a signal strength indicator amplifier) and one transistor amplifier to amplify the detected audio signals.

All components except Tuning capacitor and ferrite bar antenna are mounted on a printed circuit board P150.

The AM signals induced in a ferrite bar antenna are applied to the input of RF amplifier (pin ①) through a capacitor of C151 and amplified to the level required for overcoming the conversion noises, thus giving good S/N performance. The tuned circuits inserted in both output and input circuit of RF amplifier assure very high image and spurious rejection performance.

Thus amplified and selected AM signals are then applied to one input of Mixer section (pin ⑥) through a coupling capacitor C158. While the local oscillator voltage is injected to the other input of the section (pin ⑤) through a capacitor C157. Then both AM signals and oscillating

voltage are mixed and converted into 455KHz intermediate frequency. The resulting IF signal is applied to the first IF transformer L153 consisting of one ceramic filter and two tuned circuits.

The output of L153 is led to the IF amplifier's input (pin ⑦) through a coupling capacitor C169 and amplified to the sufficient level to drive the detector. The output of IF amplifier (pin ⑧) is led to the detector's input (pin ⑫) through IF filter L154. The detected audio signal derived from pin ⑪ is filtered and amplified and final audio output is obtained from the collector of H152 and applied to the TAPE MONITOR OUT jacks through the function switch.

The DC component of the detected IF signal is used as a AGC voltage to control emitter current of RF and IF amplifier through the resistor R154 and R155. A part of the DC component is also applied to the signal strength indication amplifier incorporated in the IC. The output appears at pin ⑭ and is level adjusted by R152, indicated on the signal strength meter M004.

2.1 Suggestions for AM Tuner trouble shooting

Check for broken AM bar antenna, next try to tune station by rotating fly-wheel tuning knob slowly and observe the AM signal strength meter whether it deflects or not. If the signal strength meter gives a deflection at several frequencies received, no failure may exist in the stages at least preceding final IF transformer L154. Next connect a oscilloscope to the test point ③ or J157 and check for audio signals with the tuning meter deflected. If the signal strength meter does not deflect, check the local oscillator circuit. Normal oscillating voltage at the hot end of the oscillator tuning capacitor is about 1.5 or 3 volts, varying with tuning capacitor position. When measuring oscillating voltage use a RF VTVM, no circuit tester gives correct indication. If the local oscillator voltage is normal, check all voltage distribution in the AM circuits by using a DC VTVM and compare the measured values with those given in the schematic diagram.

3. FM TUNER

3.1 RF and IF Circuit

The FM Tuner section of the Model 4300 is divided into five functional blocks: FM Front End, IF Amplifier, Detector, Muting Control and MPX Stereo Decoding Circuit.

FM signals induced by a FM antenna are led to FM antenna coil L101 through a Balun coil. These signals are then applied to the FET RF amplifier which in turn applies its output to the next FET Mixer H102 through the triple tuned high selective circuits. The FET Mixer converts its input signal into 10.7 MHz intermediate frequency and amplifies it at the same time. The H103 is a local oscillator and its output is injected into the source of the FET Mixer, the injection voltage is about 700mV. The 10.7 MHz front end output is led to the next IF amplifier unit through a coaxial cable.

The IF amplifier unit consists of seven stages of IF amplifier and one stage of AGC amplifier. Eight pieces of ceramic filters are also used to obtain high selectivity, four stages of symmetrical diode limiters are also employed for the best limiting characteristics, improved capture ratio and AM good suppression.

A part of FM Front End output is applied to the AGC amplifier H209 and rectified its output is fed back to the gate of FET RF amplifier to decrease the gain with increased signal strength.

The signals required for signal strength indication are obtained from the five stages of IF amplifiers through coupling capacitors C252, C211, C214, C223 and C228 respectively and rectified by three pair of full wave diode circuits. Thus obtained these DC components are appropriately mixed and applied to the signal strength meter through the Meter Amplifier H316.

The IF signal sufficiently amplified through each stage of IF amplifier is finally applied to the Detector Amplifier H208. The detected audio output is led to the buffer amplifier H210 and its buffered output is led to; (a) noise amplifier H310 through resistor R378 and capacitor C333, (b) QUADRADIAL OUTPUT Jack on the rear panel through resistor R379, (c) MPX stereo decoding IC (H321) through R301 and H301.

3.1 Audio Muting and Stereo Mode Auto-Selecting Circuit

The muting circuit consisting of all solid-state electrical switching has been incorporated in the Model 4300. Three inputs control the muting function. The first is related to signal strength, the second to the noise condition at the detector and the third is derived from the DC component of the detector output. These inputs are properly matrixed and gated to provide muting free from noise and transients.

The first input of DC voltage obtained by rectifying a part of IF output signal from the H205 and H206 is applied to the base of H308 and turns on it, if the IF output is greater than predetermined level (muting threshold level). When the H308 is turned on the H309 is turned off, allowing the emitter-collector resistance increasing and the collector voltage rises about 9V. The increased collector voltage increases the gate bias voltage and turns on the switching FET H301, decreasing the source-drain resistance to near zero ohm and allowing the audio signal applied to the source to flow to the pin ② of decoding IC through the source-drain path.

When the input signal is lower than predetermined level, the DC output obtained is small and can not turn on the H308, thus the H308 keeps its turn-off stage and this makes H309 turn on, decreasing the collector voltage and turning off H301. Thus no audio signals can pass through the FET. This is the fundamental principle of the muting operation but for more elaborate muting operation the second and the third inputs are necessary.

The second input is used to protect the muting operation and MPX stereo beacon lamps from misoperation due to undesirable noises. The high frequency noises included in the detected audio signals are separated by a small capacitor C333 and amplified by the noise amplifier transistor H310 and its output is rectified by the two diodes. The rectified DC output is proportional to the noise components in the audio signals.

When there are excessive noises in the audio signals such as obtained with a station incorrectly tuned in, the rectified DC output turns on the transistor H311, decreasing the emitter-collector resistance to zero. This means the collector of H309 is short-circuited to the ground, therefore the H301 is turned off and any audio signals having excessive high frequency noises can not go through the FET's source-drain path.

The transistor H317, also, turns off when transistor H309 or H311 turns on, and turns on the transistor H303 connected to pin ⑧ on the MPX decoding IC. Pin ⑧ is therefore grounded equivalently to set the IC in the monaural mode of operation. This prevent misoperation due to undesirable noises when the FM tuner is out of tuning.

The third input is obtained from the FM discriminator circuit. The DC output so called "S" curve is applied to the gate of H312 through a resistor R281 and dividing network (R361 & R362). The DC output is zero with a station correctly tuned in, but will vary from negative to positive values or vice versa when the tuning point is deviated toward either plus or minus frequency from the correct tuning frequency.

When the DC output is increased to a greater level than that of predetermined, the increased source potential of H312 makes the transistor H315 turn on (this means the collector of H309 is short-circuited to the ground), ... H301 turn off, ... H317 turn off, ... H303 turn on. This grounds pin ⑧ of the MPX stereo decoding IC, therefore the decoder is set in the monaural mode of operation and the stereo indicator lamp turns off. When the DC output is increased to the negative predetermined level, the decreased source potential turns off the H313 which in turn makes the H314 turn on (this means the collector of H309 is short-circuited to the ground). The subsequent changes are exactly the same as that just described above.

Thus when the tuning is shifted or deviated to the certain frequencies in which undesirable noisy side-audio signals are produced, both muting and monaural/stereo Switching Transistor H303 are operated automatically and open the circuits.

With the station correctly tuned in, the bias current of the FET H312 is adjusted so that both transistor H314 and H315 are not turned on, giving no effect on the transistor H309.

3.2 MPX Stereo Decoding Circuit

The stereo composite signal from the buffer amplifier undergoes a phase compensation by R301 and C301, is applied through the muting switching FET H301 to the input terminal pin ②, of the MPX stereo decoding IC H321 on a PLL (Phase Locked Loop) basis, and decoded into the left and right stereo signals, which become available at pins ④ and ⑤ respectively. These decoded left and right stereo audio signals are introduced through a low pass filter composed of L301 to L304 and C311 to C320 for elimination of undesirable residual switching signal and through a de-emphasis network consisting of R325, R326, C321 and C322, into the npn-pnp direct coupled audio amplifier, where the signals are amplified to a required level for the output from J311 and J313. From these jacks, the audio signals are led to the TAPE MONITOR OUT jacks through the function switch. Figure 1 presents an internal block diagram showing the functions of the PLL basis MPX stereo decoding IC HA1156. The input stereo composite signal, amplified by the audio amplifier, is delivered to the phase detectors PD-1 and PD-2. A part of the stereo composite signal is also applied to the stereo decoder section. The VCO (Voltage Control Oscillator) produces a free run oscillation in the neighborhood of 76KHz with the time constant determined by a capacitor C305 and resistors R311 and R312 set on the outside of pin ⑭. The VCO output has its frequency divided into 19KHz through the two stages of the frequency divider (DIV-1 & DIV-2), and is reverted to the phase detector PD-1, which contains two input terminals designed to produce an output in proportion to the product of the two input signals. The signal applied to one of the inputs of PD-1 is the 19KHz square wave formed through frequency division of the 76KHz VCO output signal by the two stages of the frequency divider DIV-1 and DIV-2, and the 19KHz pilot signal included in the stereo composite signal as a reference signal is applied to the other input. Therefore, the output of PD-1 which has passed through the low pass filter LPF-1 provides DC output voltage in proportion to the phase variance between the two inputs. This DC output voltage is amplified by the DC amplifier, and supplied to the 76KHz VCO as a control voltage. This means that the output frequency and phase of the VCO have been phase-locked to the input pilot signal. The 38KHz sub-carrier reproduced by PLL as stated above is delivered through the stereo switch to the stereo decoder section as a switching signal, thus driving the decoder section. One of the inputs of PD-2 is given the 19KHz resulting from the frequency division completed by DIV-1 and DIV-3, whereas the other input gets the 19KHz output contained in the composite signal, and the output is provided with a DC output in proportion to the amplitude of the pilot signal.

Figure 1. Block Diagram of the HA1156

This DC output is furnished through LPF-2 to the trigger amplifier which drives the stereo indicator lamp and stereo switch. Therefore, insufficient supply of the pilot signal results in failure to light the stereo indicator and to turn on the stereo switch located in the path of the 38KHz switching signal, thereby avoiding a wrong stereo operation. H303 attached on the outside of pin ⑧ is a switching transistor for automatic monaural-stereo switchover. When the intensity of an incoming signal from an FM station is weaker than a predetermined level, this H303 is turned on and pin ⑧ is grounded, thereby developing a condition for monaural reception. For a forced monaural operation, switch the MODE switch to "MONO," and H303 comes into an "On" condition with the positive bias voltage applied to the base, and pin ⑧ is grounded, thereby establishing monaural operation. The transistor H302 connected externally to pin ⑭ is intended to stop the 76KHz oscillation of the VCO which interferes an AM signal during the reception of an AM station. When the function switch is set to "AM" position, a positive bias is charged on the base of H302, H302 is turned on, and pin ⑭ is grounded. Thus, the oscillation of the VCO is stopped, ending the interference with AM reception.

3.3 Suggestion for Trouble Shooting of FM Tuner

3.3.1 Symptom: No FM Reception

First turn on the Power switch and try to tune FM stations. Rotate the fly-wheel tuning knob slowly and observe the FM signal strength meter. If the signal strength meter deflect at several frequencies received, the tuner circuits preceding the discriminator circuit may have no failure. When no reading is obtained in the meter, check FM local oscillator circuit, using a RF VTVM. The normal local oscillator voltage is one or two volts (rms) at the tuning capacitor, depending on the tuning capacitor position. If the local oscillator voltage is normal, next check all voltage distribution in the FM Front End and IF amplifier unit and compare them with those shown in the circuit diagram. When signal strength meter deflects but no sound is obtained, check audio circuit, using high sensitive oscilloscope.

3.3.2 Symptom: No Stereo Separation

First check the "MODE" switch is in normal 2 CH position. Connect a FM RF signal generator output modulated by a stereo modulator to the rear FM antenna terminals, and check the stereo beacon is turned on or not. If not turned on, check for 19KHz VCO output signal (J310), using an oscilloscope and a frequency counter.

4. PHONO AND PRE-AMPLIFIER

Signals from the PHONO jacks are applied to the phono-amplifier mounted on P400. The amplified and RIAA equalized phono signals and signals from the tuner section, CD-4/AUX and TAPE MONITOR IN jacks are applied to the SELECTOR switch which, in turn, leads the selected signals to the TAPE MON. switch and TAPE MONITOR OUT jacks. Applied to the other section of the TAPE MON. switch are signals from the TAPE MONITOR IN jacks. The TAPE MON. switch selects the signals from the SELECTOR switch or those from the TAPE MONITOR IN jacks and the selected signals go to the DOLBY and MODE switches. Signals are then mode processed by the MODE switch and its associated circuit and applied to the tone control amplifier through the buffer amplifier and BALANCE and VOLUME controls. The bass and treble controlled signals from the tone control amplifier pass through the hi filter before they reach the main amplifier.

4.1 Mode Switch

MODE switch S002 has positions of MONO, 2 CH, DISCRETE, VARI-MATRIX, and S0 DECODER.

In the MONO position, all input signals are mixed together and delivered to all four channels.

In the 2 CH position, each pair of input signals right-front (RF) and right-rear (RR), and left-front (LF) and left-rear (LR) are mixed together. The resultant signals (RF + RR) and (LF + LR) are delivered to the pairs of RF and RR, and LF and LR channels, respectively.

In the DISCRETE position, each channel signal is separately routed to the corresponding channel.

In the VARI-MATRIX position, 2-channel stereo input signals are converted into quadraphonic signals through the vari-matrix circuit; the input right and left channel signals are fed directly to the LF and RF channels, while the signals to the LR and RR channels are synthesized from the 2-channel input signals under the control of the DIMENSION control. The LR and RR channel signal components are controlled by the DIMENSION control as shown below.

DIMENSION Control Setting	LR Output	RR Output
Minimum (FCCW)	LF + RF	RF + LF
Center	LF	RF
Maximum (FCW)	LF - RF	RF - LF

When the DIMENSION control is set to the minimum position the LR and RR channel signals become monophonic, to the center are stereophonic, and to the maximum are out of phase, thus providing vanished sound image positioning.

In the SQ DECODER position, signal sources encoded by the CBS SQ system are ideally decoded into 4-channel signals. Required for this operation is incorporation of the SQ Adaptor, Model SQA-1, into the Model 4300.

4.2 Balance Control

Signals from the buffer amplifiers are fed into the balance control circuit, in which the signals are controlled by three balancers: FRONT L-R, REAR L-R, and FRONT-REAR. By setting the FRONT-REAR balancer to the "FRONT" side and the FRONT L-R balancer to the "L" side, for example, only the front left channel is driven.

The balance control circuit is provided with the REMOTE CONTROL switch which makes the Model RC-4 Remote Control Box operative when set to the "REMOTE" position. In the "REMOTE" position the BALANCE and VOLUME controls on the Model 4300 become ineffective since signals are led to the Model RC-4. Balance and volume can be adjusted by the Model RC-4. Balance and Volume controlled signals are led to the tone control amplifier.

5. DOLBY UNIT

The Dolby units built in the Model 4300, which are two processors, allows you to monitor the Dolbyized recording sound with flat response from the loudspeakers during the Dolbyized recording on the tape recorder. The Dolby unit is inserted in front channels only.

An input signal coming to J601 (J602) is amplified by H601 (H602) and in the playback mode of operation, its output signal is led to the high-cut filter and is further amplified by H603 and H605. In the record mode of operation, the signal magnified by the H602 is directly amplified by H604 and H606. The signal magnified by H603 and H605 (H604 and H606) comes to the resistance mixing circuit of R623 and R625 (R624 and R626) and to the phase inverting circuit of H607 and H609 (H608 and H610). The output signal is fed out from J607 (J608) to the TAPE MONITOR OUT Jack or amplifiers.

Encoding and decoding in the Dolby circuit are accomplished as follows. In the record mode of operation, the signal from J606 is led to J612 and is discriminated in the frequency and level by the dynamic filter consisting of H612, resistor, and capacitor. The discriminated signal is then led to the amplifier of H614 and H616, and its output signal is fed back to the mixing circuit with in phase, thus increasing the output level at J608, i.e., "encoded". In the playback mode of operation, a part of the output signal (J607) is led to J611 and is discriminated in the frequency and level by the dynamic filter consisting of H611, resistor, and capacitor.

The discriminated signal is then led to the amplifier of H613 and H615, and its output signal is fed back to the mixing circuit with out of phase, thus decreasing the output level at J607, i.e., "decoded".

The diodes H626 to H629 function as a limiter. The attached "DOLBY PROCESSING CHART" will facilitate you to well understand the operation of the Dolby circuit.

6. 400Hz TONE

The 400Hz tone signal is a 580mV, 400Hz sine wave led to the FRONT and REAR TAPE MONITOR OUT jacks at any position of the DOLBY switch (with exception of the RECORD II position) and the SELECTOR switch.

The output signal of the 400Hz oscillator consisting of HL01 and HL02 is fed to JL02 and JL03, respectively, through the emitter follower HL03. The output levels at JL02 and JL03 are adjusted to 580mV and approximately 50mV, respectively.

The signal fed from the Dolby P.W. Board comes to JL04 and is rectified through HL06. The rectified output at JL06 is led to the meter M004.

7. DOLBY SWITCH

This switch sets the Dolby noise-reduction circuit for record or playback and also switches the Meter Mode from AM or FM SIGNAL STRENGTH to DOLBY CAL LEVEL, or vice-versa. With the DOLBY switch placed in "OFF" position, the Meter will be used as a SIGNAL-STRENGTH meter; in all other positions as a DOLBY CAL LEVEL meter.

7.1 Dolby FM

This position is used for listening to Dolbyized FM broadcasts. The Dolby FM level has been pre-adjusted by RC05 and RC06.

7.2 Play

This position is used to play back a Dolbyized source (except FM).

7.3 Off

With this position, the Dolby circuit is by-passed and the input signals are directly applied to both TAPE MONITOR OUT jacks and amplifiers.

7.4 Record I

For making a Dolbyized recording from an in-coming "flat" (non-Dolbyized) signal. When the MONITOR switch is in the SOURCE (out) position, the "flat" signal will be heard. When the MONITOR switch is in the TAPE (in) position, the "flat" signal will be heard after the Dolbyized signal from the tape has been decoded.

7.5 Record II

For making a "flat" (non-Dolbyized) recording from an in-coming Dolbyized signal. Regardless of the position of the MONITOR switch, a "flat" signal will be heard.

8. RECORD LEVEL (L) (R)

These knobs control the record level of the signals to be recorded through the Dolby unit. Adjust the knobs so that the Level Meter pointers of the tape recorder do not exceed the OVU level.

9. PLAY CAL. (L) (R)

These knobs adjust the playback outputs from a tape deck to the proper Dolby level.

10. DOLBY FM PRESET LEVEL CONTROLS

These factory-adjusted controls govern FM output level to the Dolby circuit. These controls are for the use of a qualified technician only.

11. 400Hz TONE SWITCH

This is used for calibration of the record input level of the tape deck. When the switch is depressed, the built-in oscillator operates and a sine wave signal output of 580mV will be applied to the four TAPE MONITOR OUT jacks.

12. FM DE-EMPHASIS SWITCH

At present both normal and Dolbyized FM broadcast programs are being transmitted with pre-emphasis time constant of 75 microsecond.

However if the Dolbyized FM broadcasting is approved by F.C.C., this pre-emphasis time constant for Dolbyized FM broadcast will be changed to 25 microsecond. The FM DE-EMPHASIS switch provided on the rear of Model 4300 is used for switching the time constants. After the permission of Dolbyized FM broadcasting, set the switch to 25 μ S position. This automatically change the time constant to 75 μ S while the DOLBY switch is placed in other than DOLBY FM positions (namely normal FM broadcast position), thus, the de-emphasis time constant for each normal and Dolbyized FM reception will be correctly set.

13. POWER AMPLIFIER

This power amplifier is a completely direct-coupled amplifying circuit. The transistor H701 and H702, which form the first stage of the differential amplifier, improve the DC stability. The transistor H705 is a current regulating circuit which further improves the DC stability. The transistor H707 and H708, which form the second stage of the differential amplifier, function as driver. The transistor H737 is a current regulating circuit as the load circuit H707. The transistors H713 and H714 drive the transistors H003 and H004 which form the power output stage. The transistor H711 is a transistor biasing circuit.

Excessive current flow in the power output stage is detected by the resistor R761 and the resultant variation is applied to the transistors H717, H719 and H721 and make them turned on. This decreases the base biasing current for H713 and H714. In this way the current flow in the power output stage (H003 and H004) is restricted within a safe predetermined value.

14. BTL (Balanced Transformer-less) CONNECTION

This power amplifier is designed to operate in either 2-channel or 4-channel modes, depending on the setting of the POWER MODE switch that incorporates phase-conversion and power switch for BTL connection.

With this switch placed in the 40Wx4 position, this unit operates as a 40W 4 channel amplifier. With the switch placed in the 100Wx2 position, the unit operate as a 100W 2 channel amplifier, in this case, the power output is obtained only from FRONT SPK terminals.

15. POWER SUPPLY UNIT

The power supply unit consisting of transistors H801, H802 and H803, which operates as an automatic voltage regulator provides +35V DC to all of the amplifiers except main amplifiers and +14V DC to the tuner section.

16. AUDIO TROUBLE ANALYSIS

1. Excessive line consumption
 - a. Check for shorted rectifiers H001 through H008.
 - b. Check for shorted transistors H713 through H716.
 - c. Check L003 for short.
2. No line consumption or zero bias
 - a. Check line cord, fuse, shorted H711 & H712, H727 & H728.

3. Excessive hum and noise level
 - b. Check for open rectifiers H810 & H811 or open L003.
 - a. Check filter capacitors C005, C006, C709, C710, C713, C714, C715 & C716.
 - b. Check for shorted transistor H801 and H802.
4. Parastic oscillation
 - a. Check for defective capacitors, C005, C006, C705, C706, C707, C708, C717, C718, C719, C720, C721, C722, C723 & C724.
5. Improper clipping
 - a. Check for proper adjustment of R721 and R722.

17. TEST EQUIPMENT REQUIRED FOR SERVICING

Table 1 lists the test equipment required for servicing the Model 4300 Receiver.

Item	Manufacturer and Model No.	Use
AM Signal Generator		Signal source for AM alignment.
Test Loop		Used with AM Signal generator.
FM Signal Generator	Less than 0.3% distortion	Signal source for FM alignment.
Stereo Modulator	Less than 0.3% distortion	Stereo separation alignment and trouble shooting.
Frequency Counter		MPX Oscillator adjustment (VCO).
Audio Oscillator	Weston Model CVO-100P, less than 0.02% residual distortion is required.	Sinewave and squarewave signal source.
Oscilloscope	High sensitivity with DC horizontal and vertical amplifiers.	Waveform analysis and trouble shooting and ASO alignment.
VTVM	With AC, DC, RF range	Voltage measurements.
Circuit Tester		Trouble shooting.
AC Wattmeter	Simpson, Model 380	Monitors primary power to Amplifier.
AC Ammeter	Commercial Grade (1-10A)	Monitors amplifier output under short circuit condition.
Line Voltmeter	Commercial Grade (0-150V AC)	Monitors potential of primary power to amplifier.
Variable Autotransformer (0-140V AC, 10 amps)	Powerstat, Model 116B	Adjusts level of primary power to amplifier.
Shorting Plug	Use phono plug with 600 ohm across center pin and shell.	Shorts amplifier input to eliminate noise pickup.
Output Load (8 ohms, $\pm 1\%$ 100W)	Commercial Grade	Provides 8-ohm load for amplifier output termination.
Output Load (4 ohms, $\pm 1\%$ 100W)	Commercial Grade	Provides 4-ohm load for amplifier output termination.

Table 1. Test Equipment Required for Servicing

18. AM ALIGNMENT PROCEDURE

18.1 AM IF Alignment

1. Connect a sweep generator to the J153 and an alignment scope to the test point ③.
2. Rotate each core of IF transformer L153 and L154 for maximum height and flat top symmetrical response.

18.2 AM Frequency Range and Tracking Alignment

1. Set AM signal generator to 525KHz. Turn the tuning capacitor fully closed (place the tuning pointer at the low end.) and adjust the oscillator coil L152 for maximum audio output.
2. Set the signal generator to 1650KHz. Place the tuning pointer in the high frequency end and adjust the oscillator trimmer on the oscillator tuning capacitor for maximum audio output.
3. Repeat the step 1 and 2 until no further adjustment is necessary.
4. Set the generator to 600KHz and tune the receiver to the same frequency and adjust a slug core of AM ferrite rod antenna and RF coil L151 for maximum output.
5. Set the generator to 1400KHz and tune the receiver to the same frequency and adjust both trimming capacitors of antenna and RF tuned circuit for maximum output.
6. Repeat the step 4 and 5 until no further adjustment is necessary.

Note: During tracking alignment reduce the signal generator output as necessary to avoid AGC action.

18.3 AM Signal Strength Meter Adjustment

Set the AM Signal generator to 1000KHz with 74dB/m, and adjust R152 so that the signal strength meter may read 80%.

19. FM ALIGNMENT PROCEDURE

1. Connect an FM signal generator to the FM ANTENNA terminals and an oscilloscope and an audio distortion analyzer to the TAPE MONITOR OUT jacks on the rear panel.
2. Set the FM SG to 87.5MHz and provide about 3 to 5 μ V. Place the tuning pointer at the low frequency end by rotating the tuning knob and adjust the core of oscillator coil L105 to obtain maximum audio output.
3. Set the FM SG to 108.5MHz and provide about 3 to 5 μ V output. Rotate the tuning knob and place the tuning pointer at the high frequency end and adjust the trimming capacitor C106 for maximum output.
4. Repeat the step 2 and 3 until no further adjustment is necessary.
5. Set the FM SG to 90MHz and tune the receiver to the same frequency. Decrease signal generator output until the audio output level decreases with the decreasing generator output. Adjust the antenna coil L101, RF coil L102, L103 and L104 and IF transformer L106 for minimum audio distortion.
6. Set the FM SG to 106 MHz and tune the receiver to the same frequency. Adjust the trimming capacitors of antenna and RF tuning circuits for minimum distortion (C102, C103, C104, C105).
7. Repeat the step 5 and 6 until no further adjustment is necessary.
8. Adjust the secondary core (upper) of discriminator transformer L201 so that the center tuning meter pointer indicates its center at no signal applied. Set the FM SG to 98MHz and increase its output level to 1K μ V and tune the receiver to the same frequency so that the center tuning meter pointer indicates its center. Adjust the primary core (lower) of L201 for minimum distortion.
9. Set the FM SG to 98MHz with 100K μ V, and adjust R374 so that signal strength meter may read 90%.

19.1 Stereo Separation Alignment

1. Set the FM SG to provide 1K μ V at 98MHz. Tune the receiver to the same frequency so that

the center tuning meter pointer indicates its center. Then turn off the modulation of the FM SG, connect a frequency counter to test point J310 (point ©) and adjust R311 so that the frequency counter may a precisely read 19KHz.

2. Modulate the FM SG with stereo composite signal consisting of only L or R channel (of course a pilot signal must be included).
3. Adjust the trimming resistor R301 for maximum and same separation in both channels.

19.2 Muting Circuit Alignment

1. Connect a VTVM to the tap of the resistor R363 and adjust the resistor R363 until the meter reads 0.75V DC at no signal.
2. Set the FM SG to provide $1\text{K}\mu\text{V}$ at 98MHz and tune the receiver to the same frequency correctly.
3. Turn on MUTING push-switch. Shift the FM signal generator frequency to plus and minus and note both plus and minus shifted frequencies at which undesirable audio side responses are muted out. Adjust the R363 so that the same shifted frequencies mute the undesirable side response.
4. Adjust R362 for preferred frequency shift at which the muting circuit operates.

20. AUDIO ADJUSTMENT

1. Connect a VTVM to No. 11 of J036(+) and No. 9 of J036(−) and adjust the trimming resistor R739 until the VTVM reads 12mV DC. For the other channel connect the VTVM to No. 33 of J036(+) and No. 35 of J036(−) and adjust the R740 for the same reading.
2. Connect a VTVM to No. 13 of J036(+) and No. 15 of J036(−) and adjust the trimming

Figure 2. Dial Stringing

resistor R721 until the VTVM reads 0V DC. For the other channel connect the VTVM to No. 31 of J036(+) and No. 29 of J036(–) and adjust the R722 until the VTVM reads 0V DC.

21. AUTOMATIC VOLTAGE REGULATOR ADJUSTMENT

Connect a VTVM to JM03(+) and JM04(–) and adjust R806 until the VTVM reads 35V under no signal condition.

22. DOLBY ALIGNMENT PROCEDURES

For adjustment of the Dolby unit, an adjusting implement should be built up base on the attached circuit diagram. Then, using the adjusting implement proceed as follows.

1. A) Set the REC/PB switch to REC, the DOLBY ON/OFF switch to OFF (close), and the FET GATE switch to OFF (close).
 B) Adjust the semi-fixed resistor R654 until the source voltage for the FET (H612) becomes maximum (positive).
 C) Feed in 5KHz at a level to give 17.5mV at J606.
 D) Note signal level obtained at the OUTPUT terminal.
 E) Set the DOLBY ON/OFF switch to ON (OPEN) and adjust gain control (R660) for a 10 ± 0.25 dB rise at the OUTPUT terminal.
 F) Note level at OUTPUT terminal with DOLBY ON/OFF switch ON.
 G) Set the FET GATE to ON and adjust low control (R654) for a 2 ± 0.25 dB drop at OUTPUT terminal.
 H) Check the level setting at Step C) to G)
2. A) Set the REC/PB switch to PB, the DOLBY ON/OFF switch to OFF (close), and the FET GATE switch to OFF (close).
 B) Adjust the semi-fixed resistor R653 until the source voltage for the FET (H611) becomes maximum (positive).
 C) Feed in 5KHz at a level to give 44mV at J603.

Figure 3. Dolby Alignment Implement Simplified Schematic

- D) Note signal level obtained at the OUTPUT terminal.
 - E) Set the DOLBY ON/OFF switch to ON and adjust gain control (R659) for a $10 \pm 0.25\text{dB}$ fall at the OUTPUT terminal.
 - F) Note level at OUTPUT terminal with DOLBY ON/OFF switch ON.
 - G) Set the FET GATE to ON and adjust low control (R653) to give a rise of $2 \pm 0.25\text{dB}$ at the OUTPUT terminal.
 - H) Check the level setting at Step C) to G).
3. For the level adjustment, set the DOLBY switch and SELECTOR switch to the RECORD I and CD-4/AUX positions, respectively, and use the TAPE MONITOR OUT jack for the output signal. By setting the 400Hz TONE pushswitch "in", the 400Hz sine wave is fed out. Adjust the semi-fixed resistor RL11 for 580mV of the sine wave output voltage in both R and L channels. Then, set the DOLBY switch to the RECORD II position, and apply the 400Hz signal for 580mV of the output voltage. Adjust the semi-fixed resistors RL28 and RL29 so that the DOLBY LEVEL meter may point the Dolby level. Change over the METER switch, and perform this adjustment for both R and L channels.
- Next adjust the semi-fixed resistor RL12 for 580mV output level when the DOLBY switch is set to the OFF position. Check this output level after the adjustment of the level setting semi-fixed resistors RL11 and RL12. The output level must be precisely 580mV since it is a reference voltage level in the Dolby circuit.

23. ALIGNMENT PROCEDURES OF DOLBY FM RESET LEVEL CONTROLS

Connect an FM signal generator to the FM antenna. Set the modulation frequency and degree of modulation of the FM signal generator to 400Hz and 50%.

Set the FM signal generator to 98MHz and the DOLBY switch to the OFF position. Turn the Tuning knob on Model 4300 until it tunes to the 98MHz signal from the FM signal generator.

Then, set the DOLBY switch to the DOLBY FM position, and adjust the FM preset level controls RC05 and RC06 so that the DOLBY LEVEL meter may point the Dolby FM level. Change over the METER switch, and perform this adjustment for both R and L channels.

24. EXPLANATION OF THE DOLBY PROCESSING CHART

This chart shows the condition of the signals available at the speakers (SPKRS) and at the TAPE MONITOR OUT terminals as a function of different control settings.

To understand the chart refer to the symbols below:

- | | |
|---|--|
|  | — Represents a signal which has not been applied to either Record or Playback Dolby circuits. The relative amplitudes of all audio frequencies remain unaltered at all levels. |
|  | — Represents a signal which has been processed by the Dolby Record circuit. The relative amplitude of the high frequencies is increased at low signal levels. |
|  | — Represents a signal which has been processed by the Dolby Playback circuit. The relative amplitude of the high frequencies is decreased at low signal levels. |
|  | — Represents a signal which has been processed by both the Record and the Playback Dolby circuits. |

These circuits are complementary. Therefore, relative amplitudes of all audio frequencies are restored to their original values.

TECHNICAL SPECIFICATIONS

PREAMPLIFIER SECTION

Dynamic Range Phono input: 96dB above 1.7 μ V equivalent noise input

Note: Dynamic Range is the ratio in dB of phono overload (110mV) to equivalent input noise (1.7 μ V).

Input Sensitivity and Impedance Phono: 1.8mV, 47 Kohms
High Level: 180mV, 100 Kohms

Output Level and Impedance Tape Recorder: 1V into 47 Kohms

Pre-Out Output Impedance 900 ohms

Phono Frequency Response 30Hz to 15KHz $\pm$ 1dB (RIAA)

Noise-Aux -80dB

Tone Controls Treble: $\pm$ 10dB at 15KHz
Bass: $\pm$ 10dB at 50Hz

Mid-Range: $\pm$ 5dB at 700Hz

Filters Hi Filter: 10KHz, 6dB per octave
Low Filter: 100Hz, 6dB per octave

Loudness Compensation 7dB at 100Hz
4dB at 10KHz

AMPLIFIER SECTION

Headphones Output 1V into 8 ohms at rated distortion

Input Sensitivity for MAIN in Front/Rear 1V

Power Output 160 Watts into 8 ohms (40W/channel x 4)
200 Watts into 8 ohms (100W/channel x 2)

Total Harmonic Distortion At or below rated power, 20Hz to 20KHz
Less than 0.15%, typically 0.1% including preamplifier (AUX)

IHF Power Bandwidth 8Hz-70KHz

Frequency Response $\pm$ 2dB, 5Hz to 70KHz
 $\pm$ 1dB, 10Hz to 30KHz

Damping Factor 2-channel Mode: 40 at 20Hz
4-channel Mode: 50 at 20Hz

FM SECTION

Quieting Slope 1.9 μ V for 30dB, 5 μ V for 55dB
10 μ V for 60dB, 50 μ V for 70dB

Ultimate Quieting 50 μ V for 70dB

Selectivity Alternate channel, better than 75dB

Capture Ratio 1.5dB

Muting Threshold Muting threshold variable from 8 μ V to 35 μ V

Stereo Separation 40dB at 1KHz, 27dB at 15KHz

Total Harmonic Distortion Stereo: Less than 0.3%
Mono: Less than 0.2%

Frequency Response $\pm$ 1dB, 30Hz to 15KHz

Total Spurious Rejection Better than 90dB

Image Rejection Better than 90dB

AM Suppression Better than 60dB

IF Rejection Better than 100dB

Antenna Impedance 300 ohm Balanced, 75 ohm unbalanced

Quadradial Output 300mV, 15 Kohms for $\pm$ 75KHz Dev.

AM SECTION

AM Sensitivity Better than 40 μ V

Selectivity Adjacent channel, 1000KHz, better than 30dB

AM Bandwidth (-6dB) 7KHz

Image Rejection 1400KHz, better than 70dB

GENERAL

Power Requirements 120V AC, 50 to 60Hz

Power Consumption — at rated power output, all channels 400 Watts
— idling (no signal) 45 Watts

Dimensions — Panel Width 19-19/64" — 490mm

— Panel Height 5-3/4" — 146mm

— Depth 15-13/64" — 386mm

Weight — Unit alone 51.6 lbs — 23.5Kg

— Packed for Shipment 62.7 lbs — 28.5Kg
